# lecture 2 Solution \& Concentration 

Edited By:
Lec. DTr. Haíder AbdufKareem Al-Mashhadani

Suspension

Precipitation

## Introduction

In the previous lecture, we have concentrated primarily on pure substanceselements, covalent compounds, and ionic compounds. Most matter with which we come into contact, however, is a mixture composed of two or more pure substances. The air we breathe is composed of nitrogen and oxygen, together with small amounts of argon, water vapor, carbon dioxide, and other gases. Seawater is composed largely of sodium chloride and water. A mixture may be heterogeneous or homogeneous.

- A mixture may be heterogeneous or homogeneous.
* A heterogeneous mixture does not have a uniform composition throughout a sample.
* A homogeneous mixture has a uniform composition throughout a sample.

A pepperoni pizza is a heterogeneous mixture, while a soft drink is a homogeneous solution.

Amalgam filling is a silver dissolve in Hg as homogenous mixture.

## Types of Mixture

A. solution is a homogeneous mixture that contains small particles. Liquid solutions are transparent.

When two substances form a solution, the substance present in the lesser amount is called the solute, and the substance present in the larger amount is the solvent. A solution with water as the solvent is called an aqueous solution.

B. Colloid is a homogeneous mixture with larger particles, often having an opaque appearance.
$>$ The particles in a colloid generally cannot be filtered from its order components, and they do not settle out on standing.
$>$ By addition, a colloid contains particles that are $1 \mathrm{~nm}-1 \mu \mathrm{~m}$ in diameter. Milk is a colloid. Homogeneous milk is an opaque homogeneous mixture contains large protein and fat molecules that do not dissolve in water.
C. Suspension is a heterogeneous mixture that contains large particles suspended in a liquid.

## $>$ A suspension contains particles greater than $1 \mu \mathrm{~m}$ in diameter.

$>$ The particles are so large that they do not dissolve in a liquid, and they can filter away from the liquid, or separated using a centrifuge.

## Health Note

$\checkmark$ Blood is a suspension containing blood cells that can be separated from liquid blood plasma by centrifugation.
$\checkmark$ Zinc oxide eugenol (ZOE) is a material created by the combination of zinc oxide and eugenol contained in oil of cloves. Mixed at a powder-to-liquid ratio of $1: 3$ to achieve a homogeneous mix. (colloid type)

This table summarizes the properties of solutions, colloids, and suspensions.

| Properties of Solutions, Colloids, and Suspensions |  |  |  |
| :--- | :--- | :--- | :--- |
| Property | System |  |  |
|  | Solution | Colloid | Suspension |
|  | Ions, atoms, <br> small molecules | Large molecules or <br> particles | Large particles or <br> aggregates |
| Particle size | $0.1-1 \mathrm{~nm}$ | $1-1000 \mathrm{~nm}$ | 1000 nm and larger |
| Effect of light | No scattering | Exhibits Tyndall effect | Exhibits Tyndall effect |
| Effect of <br> gravity | Stable, does <br> not separate | Stable, does not <br> separate | Unstable, sediment <br> forms |
| Filtration | Particles not <br> retained on filter | Particles not retained <br> on filter | Particles retained on <br> filter |
| Uniformity | Homogeneous | Homogeneous | Heterogeneous |

## Electrolytes and Nonelectrolytes

- A solute that dissolve in water to from ions conducts electricity, whereas a solute that contains only neutral molecules does not. Thus, an aqueous solution of sodium chloride, NaCl , contains $\mathrm{Na}^{+}$cations and $\mathrm{Cl}^{-}$anions and conducts electricity. An aqueous solution of hydrogen peroxide, $\mathrm{H}_{2} \mathrm{O}_{2}$, contains only neutral $\mathrm{H}_{2} \mathrm{O}_{2}$ molecules in $\mathrm{H}_{2} \mathrm{O}$, so it does not conduct electricity.
- A substance that conducts an electric current in water is called an electrolyte. NaCl is an electrolyte.
- A substance that does not conduct an electric current in water is called $\boldsymbol{a}$ nonelectrolyte. $\mathrm{H}_{2} \mathrm{O}_{2}$ is a nonelectrolyte.

## Classification of Electrolytes

Electrolytes are substances which, when dissolved in water, break up into cations (positive-charged ions) and anions (negative-charged ions). We say they ionize. Strong electrolytes ionize completely ( $100 \%$ ), while weak electrolytes ionize only partially (usually on the order of $1-10 \%$ ). That is, the principal species in solution for strong electrolytes are ions, while the principal specie in solution for weak electrolytes is the un-ionized compound itself.

Electrolytes can be classified as strong or weak, on the extent that the compound dissociates (forms ions).

- A strong electrolyte dissociates completely to form ions when it dissolves in water. Like NaCl .
$\checkmark$ strong acids $\mathrm{HCl}, \mathrm{HBr}, \mathrm{HI}, \mathrm{HNO}_{3}, \mathrm{HClO}_{3}, \mathrm{HClO}_{4}$, and $\mathrm{H}_{2} \mathrm{SO}_{4}$
$\checkmark$ strong bases $\mathrm{NaOH}, \mathrm{KOH}, \mathrm{LiOH}, \mathrm{Ba}(\mathrm{OH})_{2}$, and $\mathrm{Ca}(\mathrm{OH})_{2}$
$\checkmark$ salts $\mathrm{NaCl}, \mathrm{KBr}, \mathrm{MgCl}_{2}$, and many, many more
- A weak electrolyte dissolves in water to yield largely uncharged molecules, but small fraction of the molecules form ions. Like ammonia $\mathrm{NH}_{3}$
$\checkmark$ weak acids $\mathrm{HF}, \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ (acetic acid), $\mathrm{H}_{2} \mathrm{CO}_{3}$ (carbonic acid), $\mathrm{H}_{3} \mathrm{PO}_{4}$ (phosphoric acid), and many more
$\checkmark$ weak bases NH 3 (ammonia), $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$ (pyridine), and several more, all containing " N "

Figure 7.2 Classification of Matter

|  | Electrolytes | Nonelectrolytes |
| :---: | :---: | :---: |
| Definition | Electrolytes are substances <br> that produce ions when <br> dissolved in a solvent | Nonelectrolytes are substance <br> that cannot produce ions <br> when dissolved in a solvent |
| Production of <br> Ions | Dissociate into ions | Cannot dissociate into ions |
| Polarity | Polar compounds | Nonpolar compounds |
| Electrical <br> Conductivity | Can conduct electricity <br> when dissolved in a <br> solvent | Cannot conduct electricity |

## Saliva as Electrolyte

Saliva is essential to all aspects of oral health. Among its important functions are cleansing, provision of antimicrobial characteristics via enzymes (e.g., lysozyme and lactoferrin), and the remineralization of the dental enamel surface.

The primary component of saliva, amounting to $99 \%$ of the total, is water. The other constituents are electrolytes and organic substances such as enzymes and proteins. The pH of saliva falls in the range of 6.0-7.5.

Calcium and phosphate ions are especially important in the natural remineralization process.

| Substance | Concentration in mmol/L |
| :--- | :--- |
| Calcium (Total) | 1.43 |
| Phosphate (Total) | 5.10 |
| Chloride | 23.2 |
| Sodium | 10.1 |
| Potassium | 22.7 |
| Ammonium | 4.35 |
| Magnesium | 0.21 |

## Concentrations Units

In using a solution in the laboratory or in administering the proper dose of a liquid medication, we must know its concentration-how much solute is dissolved in a given amount of solution. Concentration can be measured in several different ways that use mass, volume, or moles. Two useful measures of concentration are reported as percentages - that is, the number of grams or milliliters of solute per 100 mL of solution.

## 1. Weight/Volume Percent

One of the most common measures of concentration is weight/volume percent concentration, (w/v)\%-that is, the number of grams of solute dissolved in 100 mL of solution. Mathematically, weight/volume percent is calculated by dividing the number of grams of solute in a given number of milliliters of solution, and multiplying by $100 \%$.

$$
\begin{array}{|c|c|c|}
\hline \begin{array}{c}
\text { Weight/volume } \\
\text { percent concentration }
\end{array} & (\mathrm{w} / \mathrm{v}) \%=\frac{\text { mass of solute }(\mathrm{g})}{\text { volume of solution }(\mathrm{mL})} \times 100 \% \text {, }{ }^{2} \times 1
\end{array}
$$

For example, vinegar contains 5 g of acetic acid dissolved in 100 mL of solution, so the acetic acid concentration is $5 \%(\mathrm{w} / \mathrm{v})$.

$$
(\mathrm{w} / \mathrm{v}) \%=\frac{5 \mathrm{~g} \text { acetic acid }}{100 \mathrm{~mL} \text { vinegar solution }} \times 100 \%=5 \%(\mathrm{w} / \mathrm{v}) \text { acetic acid }
$$

Note that the volume used to calculate concentration is the final volume of the solution, not the volume of solvent added to make the solution. A special flask called a volumetric flask is used to make a solution of a given concentration. The solute is placed in the flask and then enough solvent is added to dissolve the solute by mixing. Next, additional solvent is added until it reaches a calibrated line that measures the final volume of the solution.
a. Add the solute.

b. Add the solvent.

To make a solution of a given concentration: (a) add a measured number of grams of solute to a volumetric flask; (b) then add solvent to dissolve the solid, bringing the level of the solvent to the calibrated mark on the neck of the flask.

Example: Chloraseptic sore throat spray contains 0.35 g of the antiseptic phenol dissolved in 25 mL of solution. What is the weight/volume percent concentration of phenol?

## Solution:

Use the formula $(\mathrm{w} / \mathrm{v}) \%=($ grams of solute $) /(\mathrm{mL}$ of solution $) \times 100 \%$.

$$
(\mathrm{w} / \mathrm{v}) \%=\frac{0.35 \mathrm{~g} \text { phenol }}{25 \mathrm{~mL} \text { solution }} \times 100 \%=1.4 \%(\mathrm{w} / \mathrm{v}) \text { phenol }
$$

Answer

## 2. Volume/Volume Percent

When the solute in a solution is a liquid, its concentration is often reported using volume/volume percent concentration, ( $\mathrm{v} / \mathrm{v}$ ) \% - that is, the number of milliliters of solute dissolved in 100 mL of solution. Mathematically, volume/volume percent is calculated by dividing the number of milliliters of solute in a given number of milliliters of solution, and multiplying by $100 \%$.

```
    Volume/volume
    percent concentration
    (v/v)% = \frac{volume of solute (mL)}{\mathrm{ volume of solution (mL)}}\times100%
```

For example, a bottle of rubbing alcohol that contains 70 mL of 2-propanol in 100 mL of solution has a $70 \%(\mathrm{v} / \mathrm{v})$ concentration of 2-propanol.

$$
(\mathrm{v} / \mathrm{v}) \%=\frac{70 \mathrm{~mL} 2 \text { 2-propanol }}{100 \mathrm{~mL} \text { rubbing alcohol }} \times 100 \%=70 \%(\mathrm{v} / \mathrm{v}) \text { 2-propanol }
$$

## 3. Using a Percent Concentration as a Conversion Factor

Percent concentration can be used as a conversion factor to relate the amount of solute (either grams or milliliters) to the amount of solution. For example, ketamine, an anesthetic especially useful for children, is supplied as a $5.0 \%(\mathrm{w} / \mathrm{v})$ solution, meaning that 5.0 g of ketamine are present in 100 mL of solution. Two conversion factors derived from the percent concentration can be written.

$$
\begin{aligned}
& 5.0 \%(\mathrm{w} / \mathrm{v}) \text { ketamine } \quad \frac{5.0 \mathrm{~g} \text { ketamine }}{100 \mathrm{~mL} \text { solution }} \quad \text { or } \quad \frac{100 \mathrm{~mL} \text { solution }}{5.0 \mathrm{~g} \text { ketamine }} \\
& \begin{array}{l}
\text { weight/volume } \\
\text { percent concentration }
\end{array}
\end{aligned}
$$

We can use these conversion factors to determine the amount of solute contained in a given volume of solution, or to determine how much solution contains a given number of grams of solute.

Example: A saline solution used in intravenous drips for patients who cannot take oral fluids contains $0.92 \%$ (w/v) NaCl in water. How many grams of NaCl are contained in 250 mL of this solution?

## Solution:

1. Identify the known quantities and the desired quantity.
$0.92 \% ~(\mathrm{w} / \mathrm{v}) \mathrm{NaCl}$ solution 250 mL
known quantities
$? \mathrm{~g} \mathrm{NaCl}$
desired quantity
2. Write out the conversion factors.

- Set up conversion factors that relate grams of NaCl to the volume of the solution using the weight/volume percent concentration.

$$
\frac{100 \mathrm{~mL} \text { solution }}{0.92 \mathrm{~g} \mathrm{NaCl}} \text { or } \frac{0.92 \mathrm{~g} \mathrm{NaCl}}{100 \mathrm{~mL} \text { solution }} \begin{gathered}
\text { Choose this conversion } \\
\text { factor to cancel } \mathrm{mL}
\end{gathered}
$$

3. Solve the problem.

- Multiply the original quantity by the conversion factor to obtain the desired quantity.

$$
250 \mathrm{mLL} \times \frac{0.92 \mathrm{~g} \mathrm{NaCl}}{100 \mathrm{~mL} \text { solution }}=2.3 \mathrm{~g} \mathrm{NaCl}
$$

## 4. Parts Per Million (ppm)

When a solution contains a very small concentration of solute, concentration is often expressed in parts per million (ppm). Whereas percent concentration is the number of parts per million is the number of "parts" in $1,000,000$ parts of solution. The "parts" may be expressed in either mass or volume units as long as the same unit is used for both the numerator and denominator.

$$
\begin{array}{|c|cc|}
\hline \text { Parts per million } & \mathrm{ppm} & =\frac{\text { mass of solute }(\mathrm{g})}{\text { mass of solution }(\mathrm{g})} \times 10^{6} \\
& \text { or } \\
& \mathrm{ppm} & =\frac{\text { volume of solute }(\mathrm{mL})}{\text { volume of solution }(\mathrm{mL})} \times 10^{6}
\end{array}
$$

A sample of seawater that contains 1.3 g of magnesium ions in $10^{6} \mathrm{~g}$ of solution contains 1.3 ppm of magnesium.

$$
\mathrm{ppm}=\frac{1.3 \mathrm{~g} \text { magnesium }}{10^{6} \mathrm{~g} \text { seawater }} \times 10^{6}=1.3 \mathrm{ppm} \text { magnesium }
$$

Parts per million is used as a concentration unit for very dilute solutions. When water is the solvent, the density of the solution is close to the density of pure water, which is $1 \mathrm{~g} / \mathrm{mL}$ at room temperature. In this case, the numerical value of the denominator is the same no matter if the unit is grams or milliliters. Thus, an aqueous solution that contains 2 ppm of MTBE (tert-butyl methyl ether), a gasoline additive and environmental pollutant, can be written in the following ways:

$$
\begin{aligned}
& \frac{2 \mathrm{~g} \mathrm{MTBE}}{10^{6} \mathrm{~g} \text { solution }} \times 10^{6}=\frac{2 \mathrm{~g} \mathrm{MTBE}}{10^{6} \mathrm{~mL} \text { solution }} \times 10^{6}=2 \mathrm{ppm} \text { MTBE } \\
& 10^{6} \mathrm{~mL} \text { has a mass of } 10^{6} \mathrm{~g} .
\end{aligned}
$$

Example: What is the concentration in parts per million of DDT (Dichlorodiphenyltrichloroethane) in the tissues of a seabird that contains 50 mg of DDT in $1,900 \mathrm{~g}$ of tissue? DDT, a nonbiodegradable pesticide that is a persistent environmental pollutant, has been banned from use in the United States since 1973.

## Solution:

- Use the formula ppm $=(\mathrm{g}$ of solute $) /(\mathrm{g}$ of solution $) \times 10^{6}$.

1. Convert milligrams of DDT to grams of DDT so that both the solute and solution have the same unit.

$$
\text { 50. } \mathrm{mg} \text { DDT } \times \frac{1 \mathrm{~g}}{1000 \mathrm{mg}}=0.050 \mathrm{~g} \mathrm{DDT}
$$

2. Use the formula to calculate parts per million.

$$
\frac{0.050 \mathrm{~g} \mathrm{DDT}}{1900 \mathrm{~g} \text { tissue }} \times 10^{6}=26 \mathrm{ppm} \text { DDT }
$$

Answer

## 5. Molarity and Normality

The most common measure of concentration in the laboratory is molaritythe number of moles of solute per liter of solution, abbreviated as M .
A solution that is formed from $1 \mathrm{~mol}(58.4 \mathrm{~g})$ of NaCl in enough water to give 1 L of solution has a molarity of 1 M . A solution that is formed from $2.50 \mathrm{~mol}(146 \mathrm{~g})$ of NaCl in enough water to give 2.50 L of solution is also a 1 M solution. Both solutions contain the same number of moles per unit volume.

$$
\begin{array}{ll}
M=\frac{\text { Moles of Solute }(\mathrm{mol})}{V(L)} & M=\frac{\text { Weight }(\mathrm{wt.})}{M \cdot W t} \times \frac{1 \cdots}{V(\mathrm{ml})} \\
N=\frac{\text { Equivelents of Solute }(\mathrm{Eq})}{V(L)} & N=\frac{W e i g h t(w t .)}{E q \cdot W t} \times \frac{1 \cdots}{V(\mathrm{ml})}
\end{array}
$$

Molarity is a conversion factor that relates the number of moles of solute to the volume of solution it occupies. Thus, if we know the molarity and volume of a solution, we can calculate the number of moles it contains. If we know the molarity and number of moles, we can calculate the volume in liters.

- To calculate the volume of solution... ...rearrange the equation for molarity (M):

$$
V(L)=\frac{\text { Moles of Solute }(\mathrm{mol})}{M}
$$

- To calculate the moles of solute... ...rearrange the equation for molarity (M):

$$
\text { Moles of Solute }(\mathrm{mol})=\mathrm{Mx} \mathrm{~V}(\mathrm{~L})
$$
